

# Genetic Algorithms

Note: today and tomorrow, we will go through lots and lots of examples of components of Evolutionary Algorithms

(I will give you lots of building blocks to experiment with later...)

# GA Quick Overview

- Developed: USA in the 1970' s
- Early names: J. Holland and K. DeJong (1975)
- Typically applied to:
  - Discrete & continuous optimization
- Attributed features:
  - not too fast
  - good heuristic for combinatorial problems
- Special Features:
  - Traditionally emphasizes combining information from good parents (crossover)
  - many variants, e.g., reproduction models, operators

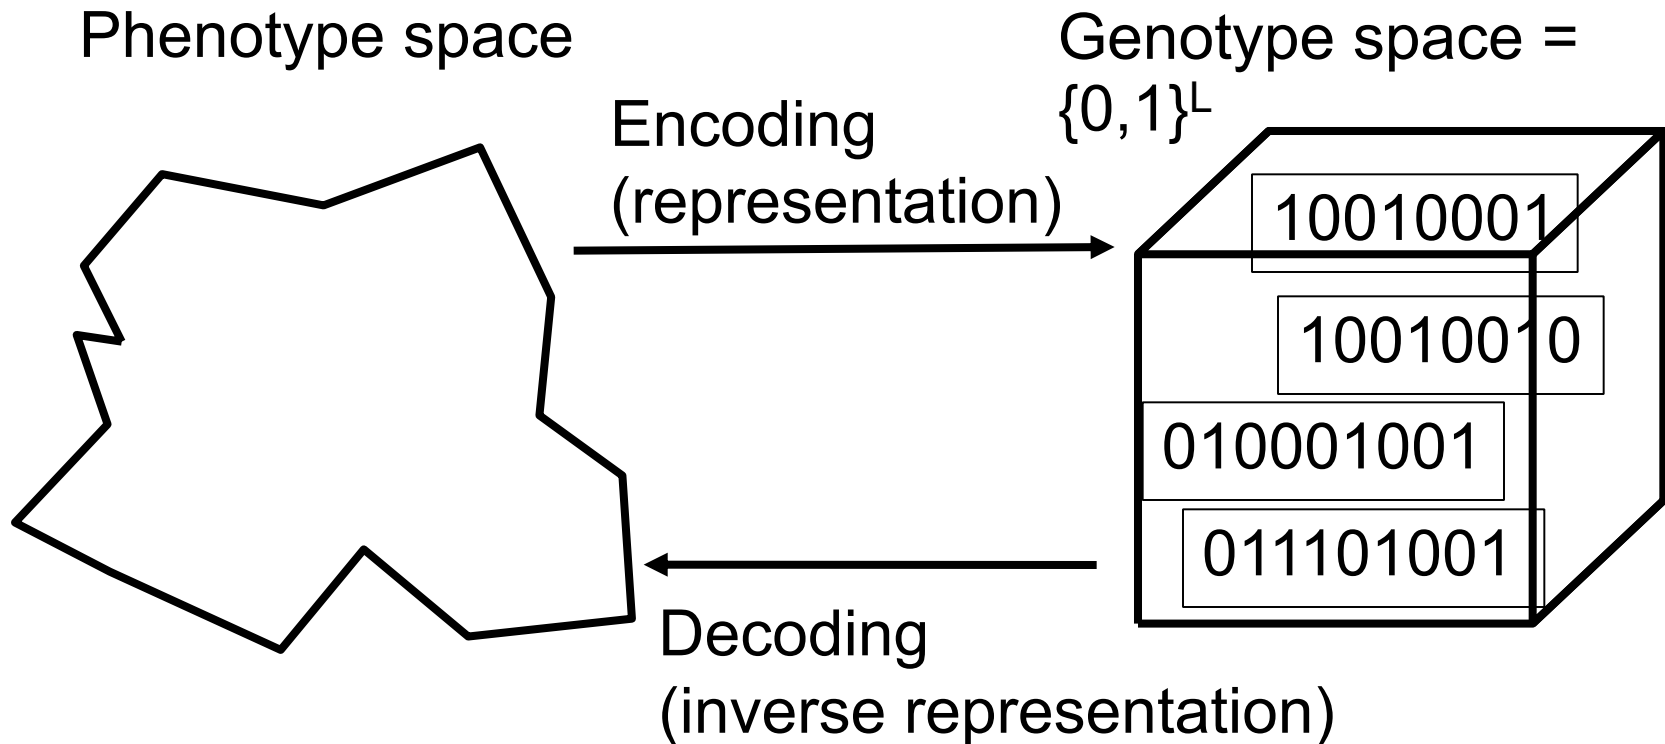

# Genetic algorithms

- Holland's original GA is now known as the simple genetic algorithm (SGA)
- Other GAs use different:
  - Representations
  - Mutations
  - Crossovers
  - Selection mechanisms

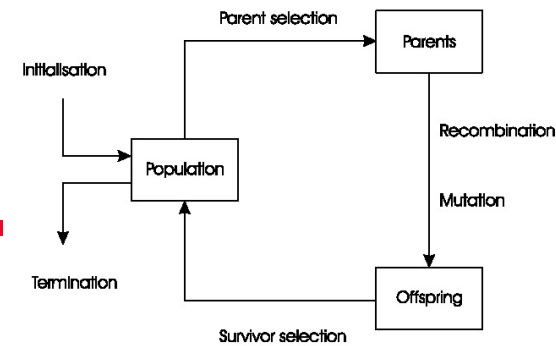

# SGA technical summary

Representation	Binary strings
Recombination	N-point or uniform
Mutation	Bitwise bit-flipping with fixed probability
Parent selection	Fitness-proportionate
Survivor selection	All children replace parents
Speciality	Emphasis on crossover

# Representation

# SGA reproduction cycle

1. Select parents for the mating pool  
(size of mating pool = population size)
2. For each consecutive pair apply crossover with probability  $p_c$  , otherwise copy parents
3. For each offspring apply mutation (bit-flip with probability  $p_m$  independently for each bit)
4. Replace the whole population with the resulting offspring

# SGA operators: Selection

Main idea: better individuals get higher chance

- Chances proportional to fitness
- Implementation: roulette wheel technique
  - Assign to each individual a part of the roulette wheel
  - Spin the wheel n times to select n individuals

18 red, 18 black, 1 green  
→ 37 numbers in total

fitness(A) = 3

fitness(B) = 1

fitness(C) = 2

# SGA operators: 1-point crossover

- Choose a random point on the two parents
- Split parents at this crossover point
- Create children by exchanging tails
- $P_c$  typically in range (0.6, 0.9)

# SGA operators: mutation

- Alter each gene independently with a probability  $p_m$
- $p_m$  is called the mutation rate
  - Typically between  $1/\text{pop\_size}$  and  $1/\text{chromosome\_length}$

parent

1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Here: 18 bits

# An example [Goldberg '89]

- Simple problem:  $\max f(x)=x^2$  over  $\{0,1,\dots,31\}$
- GA approach:
  - Representation: binary code, e.g.  $01101 \leftrightarrow 13$
  - Population size: 4
  - 1-point crossover, bitwise mutation
  - Roulette wheel selection
  - Random initialization
- We show one generational cycle done by hand

# The simple GA

- Has been subject of many (early) studies
  - For a very long time often used as benchmark for novel GAs (not nowadays anymore...)
- Shows many shortcomings, e.g.,
  - Representation is too restrictive
  - Mutation & crossovers only applicable for bit-string & integer representations
  - Generational population model (step 6 in SGA repr. cycle) can be improved with explicit survivor selection

# Alternative Crossover Operators

Performance with 1 Point Crossover depends on the order that variables occur in the representation

- more likely to keep together genes that are near each other
- can never keep together genes from opposite ends of string
- this is known as *Positional Bias*
- can be exploited if we know about the structure of our problem, but this is not usually the case

# n-point crossover

- Choose  $n$  random crossover points
- Split along those points
- Glue parts, alternating between parents
- Generalisation of 1 point (still some positional bias)

# Uniform crossover

- Assign 'heads' to one parent, 'tails' to the other
- Flip a coin for each gene of the first child
- Make an inverse copy of the gene for the second child
- Inheritance is independent of position

parents

0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

# Crossover OR mutation?

- A long debate: which one is better / necessary / main vs. background

**Onlineclicker.org: ZZZZ**

Think by yourself (no talking!):

What is best?

1. mutation
2. crossover

# Crossover OR mutation?

- A long debate: which one is better / necessary / main vs. background

**Onlineclicker.org: 8818**

Think by yourself (no talking!):

What is best?

1. mutation
2. crossover

# Crossover OR mutation?

- A long debate: which one is better / necessary / main vs. background

**Discuss with your neighbours / in  
the Zoom Breakout Room!**

What is best?

1. mutation
2. crossover

# Crossover OR mutation?

- A long debate: which one is better / necessary / main vs. background

**Onlineclicker.org: 8819**

What is best?

1. mutation
2. crossover

# Crossover OR mutation?

- A long debate: which one is better / necessary / main vs. background
- Answer (at least, rather wide agreement):
  - it depends on the problem, but
  - in general, it is good to have both
  - both have different roles
  - mutation-only-EA is possible, crossover-only-EA generally would not work

# Crossover OR mutation? (cont' d)

**Exploration:** Discovering promising areas in the search space, i.e., gaining information on the problem.

**Exploitation:** Optimising within a promising area, i.e., using existing information.

- Crossover is explorative, it makes a *big* jump to an area somewhere “in between” two (parent) areas
- Mutation is exploitative, it creates random *small* diversions, thereby staying near (in the area of) the parent  
(note: in different stages of the optimisation, the operators can have different effects) [note: not always true]

# Crossover OR mutation? (cont' d)

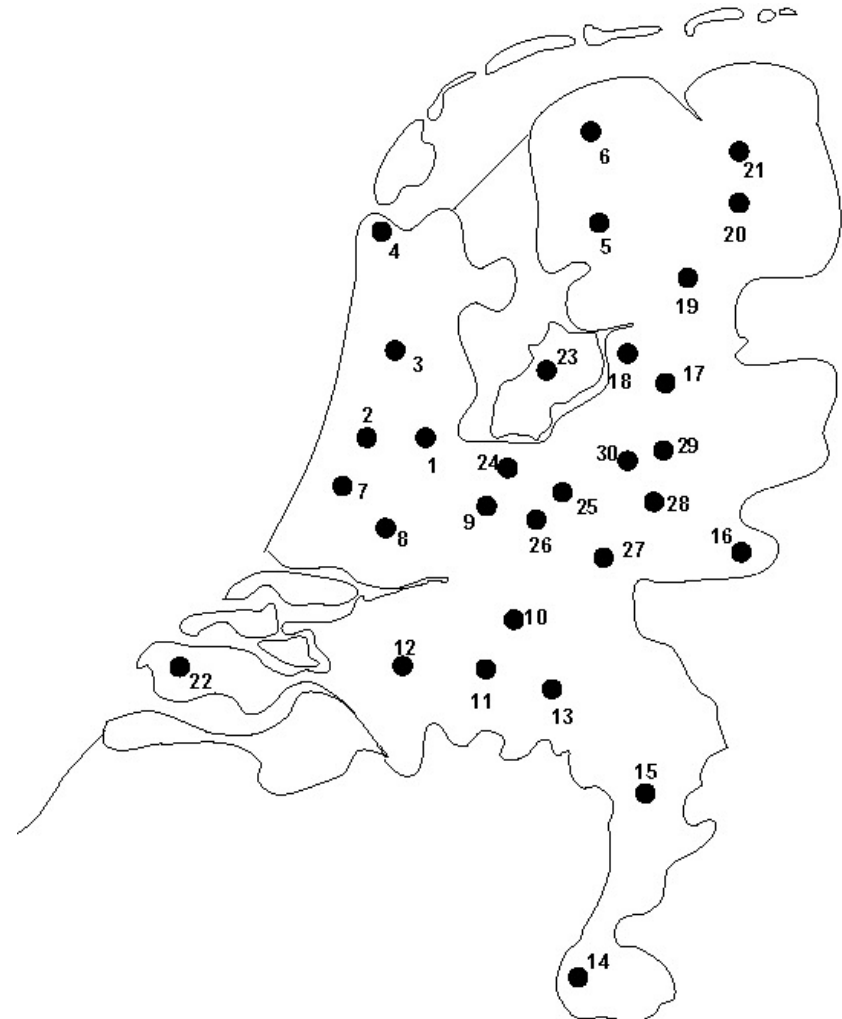

- Only crossover can combine information from two parents
- Only mutation can introduce new information (alleles)
- Crossover does not change the allele frequencies of the population  
(thought experiment: 50% 0's on first bit in the population, ?%  
after performing  $n$  crossovers)
- To hit the optimum you often need a 'lucky' mutation

# Permutation Representations

- Ordering/sequencing problems form a special type
- Task is (or can be solved by) arranging some objects in a certain order
  - Example: sort algorithm: important thing is which elements occur before others (order)
  - Example: Travelling Salesman Problem (TSP): important thing is which elements occur next to each other (adjacency)
- Solutions to these problems are generally expressed as permutations:
  - if there are  $n$  variables then the representation is as a list of  $n$  integers, each of which occurs exactly once

# Permutation representation: TSP example

- Problem:
  - Given  $n$  cities
  - Find a complete tour with minimal length
- **TSP is NP-hard**
- Encoding:
  - Label the cities  $1, 2, \dots, n$
  - One complete tour is one permutation (e.g. for  $n=4$   $[1,2,3,4]$ ,  $[3,4,2,1]$  are OK)
- Search space is BIG:  
for 30 cities there are  $30! \approx 10^{32}$  possible tours

# Mutation operators for permutations

- Normal mutation operators lead to inadmissible solutions
  - e.g. bit-wise mutation: let gene  $i$  have value  $j$
  - changing to some other value  $k$  would mean that  $k$  occurred twice and  $j$  no longer occurred
- Therefore must change at least two values
- Mutation parameter now reflects the probability that some operator is applied once to the whole string, rather than individually in each position

# Insert Mutation for permutations

- Pick two allele values at random
- Move the second to follow the first, shifting the rest along to accommodate
- Note that this preserves most of the order and the adjacency information

# Swap mutation for permutations

- Pick two alleles at random and swap their positions
- Preserves most of adjacency information (4 links broken), disrupts order more

# Inversion mutation for permutations

- Pick two alleles at random and then invert the substring between them.
- Preserves most adjacency information (only breaks two links) but disruptive of order information

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

1	5	4	3	2	6	7	8	9
---	---	---	---	---	---	---	---	---

# Scramble mutation for permutations

- Pick a subset of genes at random
- Randomly rearrange the alleles in those positions

(note: subset does not have to be contiguous)

# Crossover operators for permutations

- “Normal” crossover operators will often lead to inadmissible solutions

- Many specialized operators have been devised which focus on combining order or adjacency information from the two parents

# Order crossover (version 1)

The idea is to preserve relative order that elements occur.

Informal procedure:

1. Choose an arbitrary part from the first parent
2. Copy this part to the first child
3. Copy the numbers that are not in the first part, to the first child:
  - starting right from cut point of the copied part,
  - using the **order** of the second parent
  - and wrapping around at the end
4. Analogous for the second child, with parent roles reversed

# Order crossover (version 2)

The idea is to preserve relative order that elements occur.

Informal procedure:

2	3	4	5	6	7	8	9	1
---	---	---	---	---	---	---	---	---

1. Choose an arbitrary leftmost part from the first parent
2. Copy this part to the first child
3. Copy the numbers that are not in the first part, to the first child:
  - starting ~~right from cut point of the copied part~~ from the left,
  - using the **order** of the second parent
  - ~~and wrapping around at the end~~
4. Analogous for the second child, with parent roles reversed

# Order crossover example (version 1)

Copy randomly selected set from first parent

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

			4	5	6	7		
--	--	--	---	---	---	---	--	--

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

Copy rest from second parent in order 1,9,3,8,2

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

3	8	2	4	5	6	7	1	9
---	---	---	---	---	---	---	---	---

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

# Partially Mapped Crossover (PMX)

Informal procedure for parents P1 and P2:

1. Choose random segment and copy it from P1
2. Starting from the first crossover point look for elements in that segment of P2 that have not been copied
3. For each of these  $i$  look in the offspring to see what element  $j$  has been copied in its place from P1
4. Place  $i$  into the position occupied  $j$  in P2, since we know that we will not be putting  $j$  there (as is already in offspring)
5. If the place occupied by  $j$  in P2 has already been filled in the offspring  $k$ , put  $i$  in the position occupied by  $k$  in P2
6. Having dealt with the elements from the crossover segment, the rest of the offspring can be filled from P2.

Second child is created analogously

# PMX example

## Step 1

copy segment  
over

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

			4	5	6	7		
--	--	--	---	---	---	---	--	--

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

## Step 2

elements  
in the segment

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

		2	4	5	6	7		8
--	--	---	---	---	---	---	--	---

## Step 3

copy remaining  
elements over

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

9	3	2	4	5	6	7	1	8
---	---	---	---	---	---	---	---	---

Note: {5-6} and {7-8} are in the parents, but only {5-6} is in the child.

# Cycle crossover

## Basic idea:

Each allele comes from one parent *together with its position*.

## Informal procedure:

1. Make a cycle of alleles from P1 in the following way.
  - (a) Start with the first allele of P1.
  - (b) Look at the allele at the *same position* in P2.
  - (c) Go to the position with the *same allele* in P1.
  - (d) Add this allele to the cycle.
  - (e) Repeat step b through d until you arrive at the first allele of P1.
2. Put the alleles of the cycle in the first child on the positions they have in the first parent.
3. Take next cycle from second parent

# Cycle crossover example

Step 1: identify cycles

# Cycle crossover example

Step 1: identify cycles

# Cycle crossover example

Step 1: identify cycles

Step 2: copy alternate cycles into offspring

# Edge Recombination

Works by constructing a table listing which edges are present in the two parents, if an edge is common to both, mark with a +

e.g. [1 2 3 4 5 6 7 8 9] and [9 3 7 8 2 6 5 1 4]

Element	Edges	Element	Edges
1	2,5,4,9	6	2,5+,7
2	1,3,6,8	7	3,6,8+
3	2,4,7,9	8	2,7+, 9
4	1,3,5,9	9	1,3,4,8
5	1,4,6+		

# Edge Recombination

Works by constructing a table listing which edges are present in the two parents, if an edge is common to both, mark with a +

e.g. [1 2 3 4 5 6 7 8 9] and [9 3 7 8 2 6 5 1 4]

Element	Edges	Element	Edges
1	2,5,4,9	6	2,5+,7
2	1,3,6,8	7	3,6,8+
3	2,4,7,9	8	2,7+, 9
4	1,3,5,9	9	1,3,4,8
5	1,4,6+		

# Edge Recombination 2

Informal procedure once edge table is constructed

1. Pick an initial element at random and put it in the offspring
2. Set the variable current element = entry
3. Remove all references to current element from the table
4. Examine list for current element:
  - If there is a common edge, pick that to be next element
  - Otherwise pick the entry in the list which itself has the shortest list
  - Ties are split at random
5. In the case of reaching an empty list:
  - Examine the other end of the offspring is for extension
  - Otherwise a new element is chosen at random

# Edge Recombination example

[1 2 3 4 5 6 7 8 9] and  
[9 3 7 8 2 6 5 1 4]

Element	Edges	Element	Edges
1	2,5,4,9	6	2,5+,7
2	1,3,6,8	7	3,6,8+
3	2,4,7,9	8	2,7+, 9
4	1,3,5,9	9	1,3,4,8
5	1,4,6+		

Choices	Element selected	Reason	Partial result
All	1	Random	[1]
2,5,4,9	5	Shortest list	[1 5]
4,6	6	Common edge	[1 5 6]
2,7	2	Random choice (both have two items in list)	[1 5 6 2]
3,8	8	Shortest list	[1 5 6 2 8]
7,9	7	Common edge	[1 5 6 2 8 7]
3	3	Only item in list	[1 5 6 2 8 7 3]
4,9	9	Random choice	[1 5 6 2 8 7 3 9]
4	4	Last element	[1 5 6 2 8 7 3 9 4]

# Multiparent recombination

- Recall that we are not constricted by the practicalities of nature
- Noting that mutation uses 1 parent, and “traditional” crossover 2, the extension to  $a > 2$  is natural to examine
- Been around since 1960s, still rare but studies indicate some usefulness
- Three main types:
  - Based on allele frequencies, e.g., p-sexual voting generalising uniform crossover
  - Based on segmentation and recombination of the parents, e.g., diagonal crossover generalising n-point crossover
  - Based on numerical operations on real-valued alleles, e.g., centre of mass crossover, generalising arithmetic recombination operators

# Population Models

- SGA uses so-called generational model:
  - each individual survives for exactly one generation
  - the entire set of parents is replaced by the offspring
- At the other end of the scale are steady-state models (SSGA):
  - one offspring is generated per generation,
  - one member of population replaced,
- Generation Gap
  - the proportion of the population replaced
  - 1.0 for SGA,  $1/\text{pop\_size}$  for SSGA

Note: many things are possible in EAs and many things will work more or less well.

Experience is key, which is why there is a programming assignment.

# Fitness Based Competition

- Selection can occur in two places:
  - Selection from current generation to take part in mating (parent selection)
  - Selection from parents + offspring to go into next generation (survivor selection)
- Selection operators work on whole individuals
  - i.e., they are representation-independent

# Implementation example: SGA

- Expected number of copies of an individual  $i$

$$E(n_i) = \mu \cdot f(i) / \langle f \rangle$$

( $\mu$  = pop.size,  $f(i)$  = fitness of  $i$ ,  $\langle f \rangle$  sum of all fitnesses in pop.)

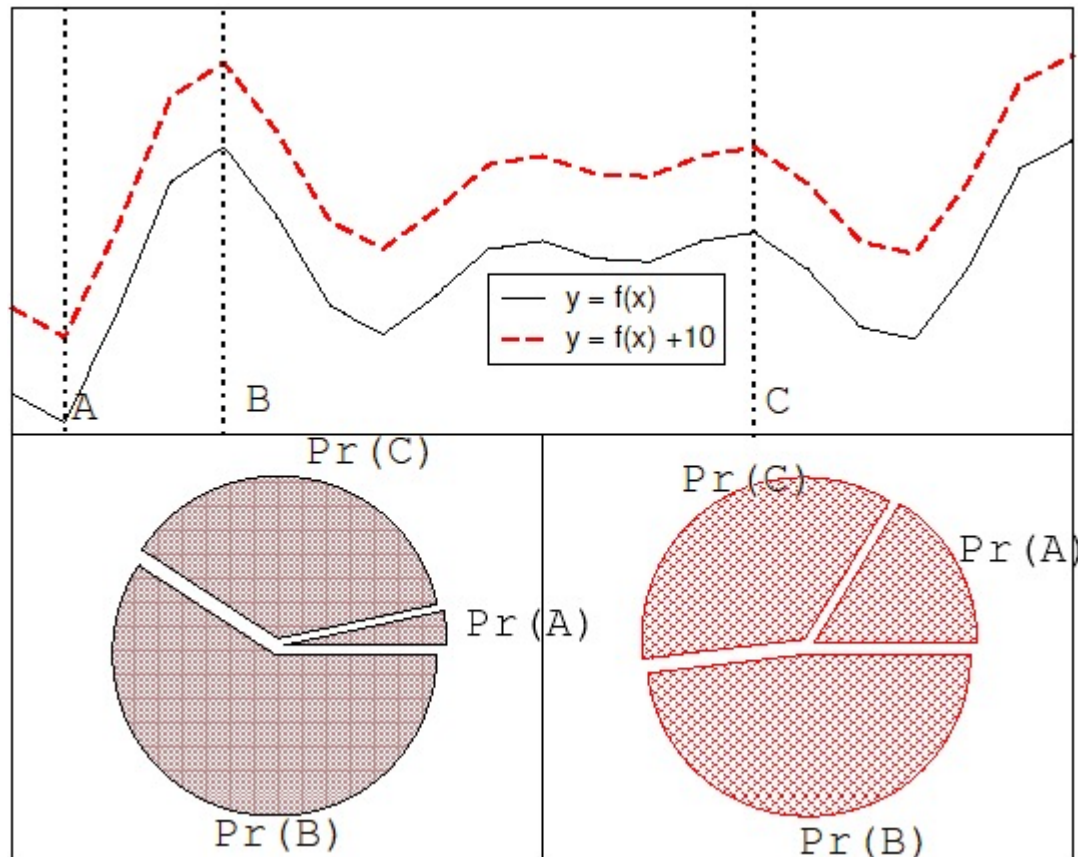

- Roulette wheel algorithm:
  - Given a probability distribution, spin a 1-armed wheel  $n$  times to make  $n$  selections
  - No guarantees on actual value of  $n_i$
- Baker's stochastic uniform sampling (SUS) algorithm:
  - $n$  evenly spaced arms on wheel and spin once
  - Guarantees  $\text{floor}(E(n_i)) \leq n_i \leq \text{ceil}(E(n_i))$

# Fitness-Proportionate Selection (FPS)

- Problems include
  - One highly fit member can rapidly take over if rest of population is much less fit: premature convergence
  - At end of runs when fitnesses are similar, lose selection pressure
  - Highly susceptible to function transposition (see next slide)
- Scaling can fix last two problems
  - Windowing:  $f'(i) = f(i) - \beta^t$ 
    - where  $\beta$  is worst fitness in this (last n) generations
  - Sigma Scaling:  $f'(i) = \max(f(i) - (\langle f \rangle - c \cdot \sigma_f), 0.0)$ 
    - where  $c$  is a constant (usually 2.0),  $\sigma_f$  is the standard deviation, and  $\langle f \rangle$  is the average fitness

# Function transposition for FPS

# Rank – Based Selection

- Attempt to remove problems of FPS by basing selection probabilities on *relative* rather than *absolute* fitness
- Rank population according to fitness and then base selection probabilities on rank where fittest has rank  $\mu$  and worst rank 1
- This imposes a sorting overhead on the algorithm, but this is usually negligible compared to the fitness evaluation time

# Tournament Selection

- All methods above rely on global population statistics
  - Could be a bottleneck esp. on parallel machines
  - Relies on presence of external fitness function which might not exist: e.g. evolving game players
- Informal Procedure:
  - Pick  $k$  members at random then select the best of these
  - Repeat to select more individuals

k=2 tournament

# Tournament Selection

- Probability of selecting  $i$  will depend on:
  - Rank of  $i$
  - Size of sample  $k$ 
    - higher  $k$  increases selection pressure
  - Whether contestants are picked with replacement
    - Picking without replacement increases selection pressure
  - Whether fittest contestant always wins (deterministic) or this happens with probability  $p$

# \*\*\* SUMMARY \*\*\*

What we have seen today:

- The so-called “Simple GA” (which focusses on bit-strings) and its components
- Several operators for working with permutations (→ group assignment!)
